

(1) MO_2

corners fill the state space
 $s(b)$

hull of the 4 corners = the whole square;
every state is a mixture of corners
 $\Rightarrow$ **no contextual state**

(2) Pentagon

a state on the far side of a face

every dispersion-free corner has $f = \sum s(a_i) \leq 2$,
 so every mixture does; but $w \equiv \frac{1}{2}$ has $f = \frac{5}{2}$
 $\Rightarrow w$ is on the **far side of the face** = **contextual**

(3) σ -essential

the leak between two hulls

the σ -additive corners reach only $g \leq m_\sigma$; the
 extra “fake” corners push the full hull to $g \leq m_{\text{full}}$.
 w has $m_\sigma < g(w) \leq m_{\text{full}}$: **outside** $\text{conv}(S_{\text{df}}^\sigma)$,
inside $\text{conv}(S_{\text{df}})$ — and no finite face sees it
